Executive Summary

Each year, many Americans look with dread at the onset of summer because they know that smog season is gearing up and they will have a hard time catching their breath. They will have to watch the weather forecasts carefully, limit outdoor activities on bad air days and risk the potential of increased medication or trips to the hospital to keep breathing. Although everyone can be affected by high ozone smog levels, those most at risk are children, the elderly, people with lung diseases including asthma, and people who work or exercise outdoors in the summer.

We have come to expect smoggy summers in the biggest cities of California, Texas, the Northeast Corridor and Lake Michigan area, but smog is now choking smaller cities across the South and Midwest as well. In fact, the majority of counties with ozone smog monitors experienced levels above what the U.S. Environmental Protection Agency (EPA) considers to be clean and safe to breathe.

Summary of findings

This report analyzes official air quality data across the country between the years 1997 and 1999. The report finds:

- 53% of the 996 ozone monitors across the country with complete data, or 523, have a three year average that exceeds the federal ozone standard over an eight-hour period.
- 56% of the 596 counties with complete monitoring data, or 333, are above the legal limit for ozone exposure.
- Thirty-three states have at least one county monitoring dirty air. There is a "Dirty Dozen" of states where more than 75% of the counties are violating the smog standard. They are: CT, DE, DC, IN, MD, NJ, NC, OH, PA, TN, VA, and WV.
- There are an estimated nearly 117 million people living in counties monitoring dirty air.
- Ten national parks have pollution levels comparable to dirty U.S. cities.

This report analyzes air quality data from 1997-99 because EPA will use these three years of data to designate counties that do not meet the National Ambient Air Quality Standard (NAAQS) for ozone over an 8-hour period. These are known as "nonattainment areas." This summer, states will submit suggested boundaries for nonattainment areas.¹ EPA will evaluate these submissions and finalize the list of nonattainment areas in early 2001. This report applies EPA's methodology to the 1997-1999 ozone data, thus providing an early indicator of the regions and counties throughout the U.S. that are likely to be declared ozone nonattainment areas in 2001. These areas will eventually be responsible for reducing emissions that contribute to ozone formation.

Smog policy decisions pending in 2000

While states with nonattainment areas are responsible for finding ways to reduce pollution, often the most effective way to reach clean air goals is to reduce emissions from the largest contributors of air pollution nationwide. In December 1999, EPA finalized a rule to reduce pollution from cars, trucks, sport utility vehicles and gasoline by up to 90% beginning in 2004. In 2000, EPA will undertake national efforts to reduce ozone pollution from other major sources. These rules will clean up power plants, diesel trucks and buses and diesel fuel in the future.

Nitrogen Oxide Controls on Power Plants: Power plants emit 25% of all nitrogen oxide (NOx) pollution, one of the main components of ozone smog. When EPA announced new ozone standards in 1997, it proposed cleaning up power plant emissions as the most cost-

effective solution for many nonattainment areas to pursue. In fact, EPA estimated that many areas faced with dirty air problems could likely meet clean air goals primarily from cleaning up power plants and through other national rules EPA had in the pipeline.

Although several states and electric utilities challenged this requirement, the U.S. Court of Appeals has upheld the requirement for states to meet their NOx emissions budgets and a deadline for SIP submissions should be decided soon.

Low-Sulfur Diesel Fuel Pollutants in the fuel determine how clean the engine can be. Currently, diesel fuel has more than 500 parts per million (ppm) of sulfur and is so dirty that engine manufacturers cannot use catalytic converters that reduce NOx and other pollutants. EPA is proposing to reduce levels to 15 ppm by mid-2006. This clean-up will allow engine manufacturers to use a broad range of pollution control equipment on new diesel engines that will significantly reduce NOx and fine particle emissions by the end of the decade, which will reduce smog. A decision is expected by December 2000.

Heavy-Duty Diesel Trucks and Buses Diesel trucks and buses are responsible for 11% of the nitrogen oxide pollution nationwide. EPA is proposing to set standards for new truck engines 95% below current levels. At this time, catalytic converters cannot function because the fuel is too dirty. By adopting an integrated approach to diesel emissions, cleaning up the fuel and engines at the same time, EPA is able to propose much more significant emission reductions and promote the use of cleaner and advanced technology. EPA will finalize engine standards with the fuel standard in December 2000.

Together, these programs offer the promise of cleaner air for many cities now faced with air quality problems. However, if states do not commit to cleaning up power plant emissions and EPA succumbs to industry and political pressure and does not regulate diesel fuel and engines, most areas will have a very difficult time identifying programs that will make it possible to reach clean air goals.

Analyzing Smog Spots: Areas Not Meeting Federal Ozone Standard

In July 1997, the U.S. EPA established a federal health-based ambient air quality standard for ozone pollution. The standard is based on average ozone concentrations measured over an 8-hour period (the former standard was based on a one-hour average). The Clean Air Act and Transportation Efficiency Act for the 21st Century requires EPA to establish the list of areas that do not meet the standard three years after setting a new ambient air quality standard. Therefore, in 2000 EPA is required to designate areas that do not meet the federal standard as "nonattainment areas." EPA is currently behind schedule, due to pending litigation over the 8-hour standard, but is proceeding with the intent of finalizing designations in early 2001.

EPA and states will be evaluating 8-hour ozone data from 1997, 1998 and 1999 in order to determine which areas are over the legal limit for smog. However, there is enough information presently available to predict with a high level of confidence

Timeline for Designation Action

March 28, 2000

EPA issued guidelines for states on determining nonattainment areas

June 30, 2000

States must recommend areas that do not meet ozone standard, including boundaries for nonattainment areas

Late Summer, 2000

EPA responds to state boundaries and allows comment from states

Early 2001

EPA will make final designations and set a date for when states must submit plans to meet the standard in which the clock for programs from states to reduce ozone pollution will begin

which areas will be declared ozone nonattainment areas under EPA's criteria. 996 of 1058 ozone monitors in 678 counties around the country have the three years of data necessary for states and EPA to make ozone attainment decisions.

Once nonattainment boundaries are finalized, states will need to develop plans to reduce emissions and smog levels to safe levels. If they fail to develop a plan, they can ultimately lose highway funds or have to offset new pollution by existing polluters. Some states want to limit the size of the nonattainment area so that polluting industries will not be subject to Clean Air Act requirements. However, by exempting these areas, a state will likely have a very difficult time identifying sufficient emission reductions to reach clean air goals.

Smog spots: By monitor

Ozone is a pervasive problem in the Eastern U.S. and California. From Texas to Maine, every state is plagued with smog. Smog is a problem in the East because of the density of population and pollution sources, as well as more hot humid weather, which is conducive to ozone formation. Since 1990, the states in the Northeast Corridor, from Washington, DC to Maine, have worked together to develop smog reduction strategies that benefit the entire region. This regional cooperation is required by the Clean Air Act Amendments of 1990 because air pollution from one state can often interfere with another state's attainment of national air quality standards. The four states surrounding Lake Michigan (IL, IN, MI, WI) also worked together because much of the lake area was affected by smog.

There appear to be other regions of nonattainment under the 8-hour standard. A region from Pittsburgh to Evansville, along the Ohio River Valley, has a string of nonattainment areas. In fact, almost every ozone monitor along the Ohio River is recording dirty air. Older coal-fired power plants dot the region, and are a likely source of the pollution problem for hundreds of miles.

Another smog zone runs along the Gulf of Mexico, from Houston to Pensacola, Florida. This area of the country is dominated by the petro-chemical industry, a significant source of hydrocarbon emissions, the other smog precursor. Southeastern cities are also faced with significant smog problems, many for the first time. Although Birmingham and Atlanta have been battling smog for some time, cities such as Macon, Huntsville, Charlotte, Raleigh-Durham, Columbia, Knoxville, Nashville, Richmond and Norfolk-Newport News are finding high smog levels as well.

Although many parts of the West have a visible air pollution problem, levels of ozone are below the national standard. Several western cities are just below the smog standard (Denver, Las Vegas, Salt Lake City) and will avoid nonattainment status for now. However, with rapid growth, these areas could find smog to be a problem in the future because attainment status is based on a three-year rolling average.

Table A summarizes the status of all monitors in every state. It lists the number of monitors in the state and the percentage of monitors that meet or exceed the ozone smog standard. It also includes the number of monitors that have incomplete (n/a) data, but if patterns continue, will likely be in nonattainment of the ozone standard in the future.

Smog spots: By county

In May 1999, the Clean Air Network released the report, *Smog Watch: Pollution and Solutions to Monitor in 1999*.³ This report analyzed 1997 and 1998 ozone data, and determined which monitors showed ozone levels above the national standard. The report found that monitors in 315 counties (51%) in 34 states had two-year averages ozone levels above the eight-hour ozone standard. Monitors in an additional 95 counties in 31 states were very close to violating the ozone standard. Only 9 states had no counties close to exceeding the ozone standard.

These predictions were fairly accurate. The summer of 1999 was especially hot in the East, with milder weather in the West. In total, 333 counties in 33 states have a three-year ozone average that exceed the national 8-hour standard, likely resulting in a nonattainment designation. Nevada has one monitor with incomplete data that is very close to exceeding the ozone standard and could be designated in the future when data are collected this year.

As you can see by the map, 12 states have experienced widespread ozone problems, with more than 75% of the counties with monitors above the smog standard. There are 17 states that have monitored clean air across their state.

Many urban areas install multiple monitors in a county to better identify the extent of the ozone problem. There are 596 counties that have at least one ozone monitor with complete data. Table B summarizes the status of monitors by county. It delineates the number and percentage of counties that meet or exceed the ozone standard. In total, nearly 117 million Americans live in counties that are monitoring dirty air. For population by county, see Appendix B.

Table B: Status of Ozone Monitors by County

Comparing Current and Likely Smog Spots

For the last 30 years, the Clean Air Act has focused on reducing peak levels of ozone smog that occur over a shorter 1-hour period. In 1990, EPA designated 98 areas that did not meet the 1-hour ozone standard. While two-thirds of those areas have managed to reduce ozone levels sufficiently to meet the standard, 1/3 of the ozone nonattainment areas remain. However, there is still a significant and pervasive ozone smog problem in the United States.

In 1997, EPA adopted an 8-hour ozone standard to address the problem of longer, more chronic exposure to smog. Recent health studies suggest that the damage caused by lower levels of ozone over a longer period can cause greater lung damage and is a more serious health threat than short term peak exposures.

As states and EPA's understanding of ozone's impact on health has become more sophisticated, we see that we are left with a growing mountain of ozone pollution in areas that have traditionally been thought to have "cleaner" air. States in the South, Midwest, and New England will likely have the most new nonattainment areas under the 8-hour standard.

If a county has a monitor violating the ozone standard, that county will be considered a nonattainment area. If that county is part of a Metropolitan Statistical Area (MSA) as defined by the U.S. Census Bureau, the entire MSA is presumed to have dirty air and will be listed as a nonattainment area. Table C identifies all the counties and MSA's expected to be nonattainment areas, based on ozone data from 1997-1999.

Table C: Current Versus Likely Nonattainment Areas

Many cities in the Midwest and Southeast have not been required to establish as many pollution controls on businesses and industry, and likely did not have to weigh how new highways and increased transportation demand impact air quality because they have been in attainment of the 1-hour ozone standard. The 8-hour ozone standard confirms that these areas have a chronic smog problem that is harming human health and the environment.

Smog Impacts on Health and Environment

Ground-level ozone, the main component of "smog," is the most pervasive air pollution problem we face in the United States. Although ozone itself is a colorless, odorless gas, it combines with particles in the air to create a yellowish haze that cloaks our cities as well as rural areas. About 1 in 3 Americans live in areas that exceed the 1-hour ozone standard.

The number of Americans living in areas exceeding the 8-hour standard is expected to be considerably higher once the affected areas have been defined.

Top 10 Smoggy Parks

1. Joshua Tree National Monument, CA
2. Great Smoky Mountains National Park, TN
3. Sequoia National Park, CA
4. Shenandoah National Park, VA
5. Cape Cod National Seashore, MA

Smog in our parks

The outdoors provides a wonderful escape from the everyday pressures of modern life — our way to connect with the natural world in which we live. Every year tens of millions of people visit our national parks and wilderness areas to enjoy some of the pristine trails, picturesque views, abundant wildlife, and to breathe clean air. When we strap on our hiking boots and travel to the mountains to escape the dirty air of the city, the last thing we want to think about is smog. Unfortunately, smog in some of our most secluded areas seriously affects our ability to breathe easily in these areas.

Smog in many of our national parks and wilderness areas is as smoggy, if not smoggier than our densely populated metropolitan areas. The smog problem has become so pervasive that some of our national parks and wilderness areas should be classified as a nonattainment areas under the 8-hour standard, based on the past 3 years of data.

Smoggy Cities vs. National Parks

Trends of smog in the parks

The Environmental Protection Agency reported that in recent years, the smog trend in some national parks has gotten worse. Smog concentrations increased at 17 of 24 National Park Service monitoring sites from 1992 to 1998, the most recent comprehensive data that is available.⁴

Ozone levels at Great Smoky Mountain National Park (our country's most visited and biologically diverse national park) and Shenandoah were 30 to 40 percent higher than the national ozone standard. This pollution can cause severe ecological and human health damage.

A study done by Harvard University found that casual day hikers in a Northeastern wilderness area experienced reduced lung function on days where ozone levels fell below the federal health standard for ozone smog. They found that healthy hikers experienced reduced lung function on days where ozone concentrations were between 21 to 74 parts per billion (ppb), significantly below the 85 ppb limit of the 8-hour standard.⁵ People who have asthma or respiratory problems were four times more susceptible to ozone than other hikers, but they discovered that even healthy non-smoking hikers experienced reduced lung function.

Other environmental effects

Ground-level ozone is also one of the most pervasive and detrimental pollutants known to affect vegetation. Ozone damages the leaves of many plants and trees, and under controlled experiments, has been demonstrated to decrease growth in sensitive species. Models have shown that at current smog levels, growth in sensitive Northeastern forests is being reduced by over 10 percent.⁶

Ground-level ozone can damage trees and other vegetation. Virtually every type of plant – conifers, broad-leaved trees, shrubs, herbs, and grasses – is susceptible to smog's effects. Ozone interferes with production and storage of starches, which reduces growth rates and can weaken plants, making them more vulnerable to disease, insect attacks, and other environmental stresses.

Not all oxides of nitrogen form ozone. There are other ways that these emissions can harm our environment as well. Nitrogen deposition into watersheds contributes to the over-fertilization of coastal and estuary water systems. Too much nitrogen in these water bodies results in increased algae growth, which limits the oxygen available to sustain fish and other aquatic life. Although the nitrogen contribution from the air varies from place to place, according to EPA's Great Waters Report, an estimated 27 percent of nitrogen pollution entering the Chesapeake Bay can be attributed to air emissions.⁷

Smog and acid rain

Nitrogen oxides are also a precursor to nitrates, a major component of acid deposition (often called acid rain), that damages both land and water systems. In many acid-sensitive streams and lakes in eastern North America, high acidity has resulted in the loss of numerous fish and aquatic species. Acid deposition also strips soils of plant nutrients and frees up aluminum, which is toxic to both plant and animal life. The highest nitrate deposition in the U.S. occurs in a 500 - mile swath from southern Illinois through Northern New York.⁸

Smog in Parks Facts

- On May 1, 1998, **Acadia National Park** was the first place on the East Coast to record an ozone violation, and have recorded higher concentrations of ozone smog than Boston and Philadelphia.
- In 1999, **Great Smoky Mountains National Park** recorded 52 days where the air pollution levels violated the federal health standard, therefore making the air unhealthy to breathe on one out of every three summer days.
- The 3-year average of ozone in **Shenandoah National Park** shows that it has recorded higher concentrations of ozone than any city in the Southeast except Atlanta, GA, and Charlotte, NC
- With just two years of data, it appears that **Indiana Dunes National Lakeshore** will be one of the dirtiest spots in Indiana.
- **Cape Cod** is routinely the dirtiest spot in MA, often exceeding pollution levels in Boston and its suburbs.
- Over the last three years, **Sequoia-Kings Canyon** and **Joshua Tree National Park** in CA have averaged 25 and 33 summer smog days respectively
- Parks on the edge: **Yosemite, Pinnacles, Los Padres** and **Channel Islands** national monuments.

Virginia's Shenandoah National Park and the Blue Ridge Mountains also fall victim to excess nitrate pollution. Currently 50% of Virginia's native brook trout streams have a reduced capacity to host trout populations due to acid deposition, and 6% are incapable of supporting trout or other fish populations because of their chronic acid state.⁹ A recent study sponsored by Trout Unlimited found that if current acid deposition levels continue the number of streams incapable of supporting fish populations is projected to climb to 35% by 2041. The study concluded that a 70% reduction in acid deposition would be required to preserve the 50% of Virginia's native brook trout streams that are currently "non-acidic" and fully capable of supporting fish populations.¹⁰

Health effects

Ozone is a powerful lung irritant, and is able to burn through lung tissue and cell walls. With prolonged exposure to unhealthy levels of ozone, the tissue in the lung walls becomes inflamed and swollen and eventually scars, making it more difficult to get enough oxygen. In addition, as the lungs become scarred, they are not able to filter bacteria and other disease-causing organisms, making it harder for the body to fight off disease and infections.¹¹ When ozone levels are high, one might experience shortness of breath, cough, burning in the eyes and chest pain when breathing deeply. Over time, repeated exposure to high ozone levels can cause as much lung damage as smoking a pack of cigarettes a day.¹²

High ozone levels are also linked to increased hospitalizations due to respiratory problems, including asthma and other chronic lung diseases. A 1999 study by Abt Associates found that high smog levels in the eastern U.S. cause 159,000 trips to the emergency room; 53,000 hospital admissions; and trigger over 6 million asthma attacks each summer.¹³

While everyone can have a reaction to high ozone levels, certain groups of people are especially sensitive to the effects of ozone at levels below the federal health-based standard:

- **Children:** Children breathe in more air per pound of body weight and spend more time playing outdoors than adults.¹⁴ They are also less likely to notice the warning signs of ozone exposure and curtail outdoor activity. Childhood asthma rates have skyrocketed in the last decade, adding to the risk from air pollution exposure.
- **People with asthma and other lung diseases:** Ozone is a powerful trigger for asthma and other respiratory diseases and ailments. Breathing during an asthma attack is likened to what a healthy person experiences when breathing through a cocktail straw. Likewise, emphysema and chronic bronchitis are worsened by exposure to ozone.
- **People who work or exercise outdoors:** Ozone has a cumulative effect, and its effects are magnified when the body is exercising or doing manual labor, such as construction or landscaping. A study by the Harvard School of Public Health and the Appalachian Mountain Club found that healthy hikers experienced decreased lung function at ozone levels well below the federal standard.¹⁵
- **Elderly:** The aging process makes the lungs weaker and more susceptible to disease. This, and chronic lung diseases, put the elderly at a higher risk of sickness or hospitalizations from ozone pollution exposure.

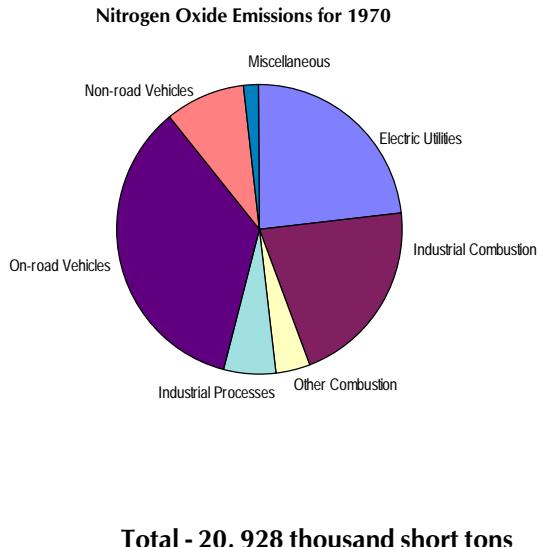

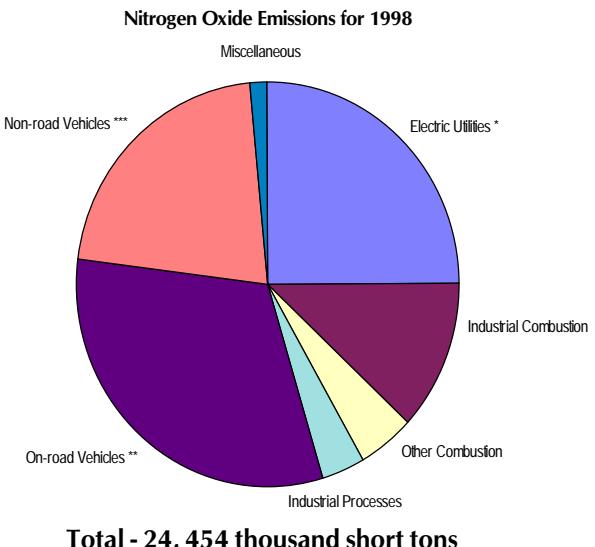

Sources of Ozone Smog Pollution

Ozone is created when nitrogen oxides (NOx) and volatile organic compounds (VOCs) bake in heat and sunlight. According to EPA, the total concentration of VOCs has dropped 42% between 1970 and 1998, while NOx emissions have increased 17%.

Nitrogen oxides

Nitrogen oxides (NOx) are a by-product of fossil fuel consumption. Burning coal, oil, gasoline and natural gas produce almost all of the nation's NOx. In 1998, on-road vehicles (cars, trucks and buses) made up the largest share of the NOx (32%), followed by electric utility fuel combustion (25%), non-road engines (boats, trains, construction and agricultural equipment) (22%), other industrial fuel combustion (17%), and miscellaneous sources (4%).

Nitrogen Oxide Emissions Across the U.S. 1998 vs. 1970

* Of the total 6103 short tons from electric utilities, 5395 or 88% are emitted by coal-burning power plants

** Of the total 7765 short tons from on-road vehicles, 2849 (37%) are from gasoline cars and motorcycles, 1917 (25%) light-duty gasoline trucks (SUV, minivans and pick-ups), 2676 (34%) from diesel vehicles.

*** Of the total 5280 total short tons from non-road engines, 2809 (53%) are from non-road diesel engines dominated by construction and farm equipment, 1008 (19%) from marine vessels, 947 (18%) from railroads.

Source: U.S. Environmental Protection Agency, National Air Quality and Emissions Trends Report, 1998

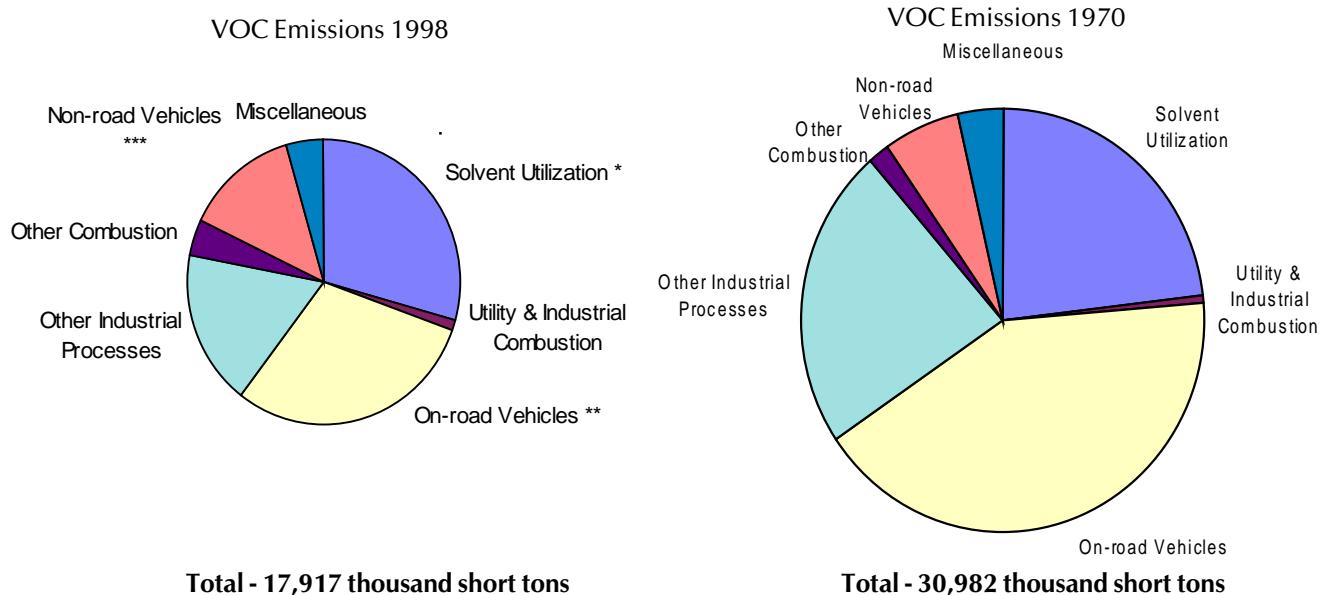

Volatile Organic Compounds

There are 58 volatile organic compounds, also known as hydrocarbons or carbonyls, targeted as a particular concern in ozone formation.¹⁷ Gasoline is one of the primary

sources for VOCs, which evaporate easily in hot weather, so cars emit VOCs while burning gasoline, but also when they are parked all day. Solvents used in industrial cleaning and manufacturing processes are large sources of VOCs. Chemical and petroleum refining emit VOCs, however, smaller businesses like dry cleaners and auto body repair shops are also significant VOC sources.

In 1998, on-road vehicles surpassed solvent use as the main source of VOCs because there was an estimated 7% decrease in solvent use from 1997 to 1998. As a result, on-road vehicles including cars, trucks and buses were responsible for 30% of the nation's VOC emissions, followed by solvent use (29%), other industrial processes (18%), non-road engines (boats, trains, construction and agricultural equipment) (14%), fuel combustion (5%), and miscellaneous sources (4%). Over the past 30 years, emissions from on-road vehicles have decreased 41%, however, they remain the largest source of hydrocarbon pollution.

Volatile Organic Compound Emissions Across the U.S. 1998 vs. 1970

*Of the total 5278 short tons of solvent utilization, 2224 (42%) was from industrial surface coatings such as paints and adhesives and 1099 (21%) was from consumer solvents used in the home.

** Of the total 5325 short tons of on-road emissions, 2832 (53%) was from gasoline cars and motorcycles, 2015 (37%) gasoline light trucks (SUVs, minivans, and pick-ups), and 222 (4%) were from diesel vehicles.

*** Of the total 2461 short tons of non-road emissions, 1794 (72%) was from non-road gasoline engines, dominated by lawn and garden equipment and recreational marine vessels, 405 (16%) diesel engines, 177 (7%) aircraft.

Source: U.S. Environmental Protection Agency, National Air Quality and Emissions Trends Report, 1998

The final ingredient needed to create ozone is hot, sunny weather that bakes the NOx and VOCs and creates the chemical reaction that leads to ozone smog. In order to reduce ozone levels, we have to reduce its components, because we have no control over the amount of sunlight and heat we receive from year to year.

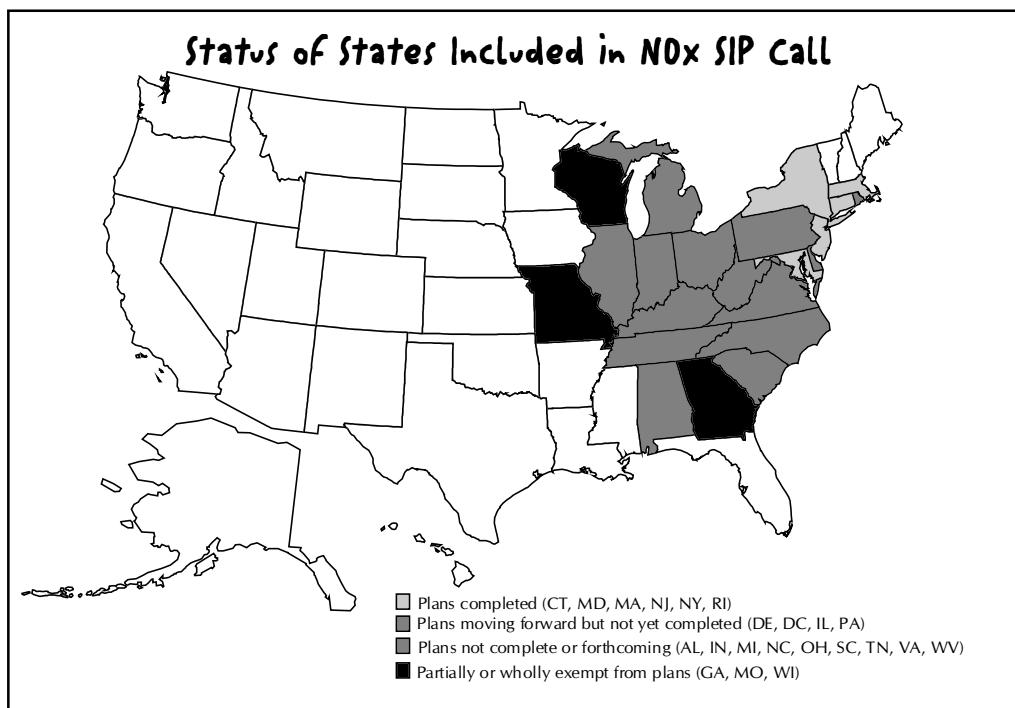

What Must Be Done: Smog & Policy Decisions for 2000

Cleaner power plants: Implement the NOx SIP Call

Coal-fired power plants are the single largest industrial polluter, and they have enjoyed a loophole in the Clean Air Act that allows older plants to avoid cleaning up to the standards met by new plants today. As a result many plants are between 30-50 years old, and are 4-10 times dirtier than new power plants built today.

According to an April 2000 report by U.S. Public Interest Research Group, the dirtiest 594 power plants emitted 5.4 million tons of NOx in 1999. If all these plants met the standards in place for new power plants, while running at the same capacity, 3.6 million tons, or 66% of the current pollution, would be avoided. Power plants currently emit 25% of the nation's nitrogen oxides, second only to cars and trucks. Power plants also emit sulfur dioxide, carbon dioxide and mercury and other toxic heavy metals, which lead to other environmental and health problems not associated with ozone smog.

In 1998, EPA issued a rule (known as the "NOx SIP Call") requiring 22 Eastern states to reduce power plant and other large industrial emissions of nitrogen oxide by 85% below 1990 levels during five summer months. As a result, each state must revise its State Implementation Plan (SIP) to account for how it will meet its assigned NOx emissions target during the summer smog season. Reductions are needed from this large region of the country to address the transport of ozone over hundreds of miles. State plans were initially due in September 1999 but court challenges have delayed the process at least one year and put progress on hold for many months.

Eight states and a number of utilities sued EPA, refusing to comply with the emission budgets assigned to them. Those states included were: Alabama, Indiana, Michigan, North Carolina, Ohio, South Carolina, Virginia, and West Virginia. Initially, the NOx SIP Call rule was put on hold by the DC Circuit of the U.S. Court of Appeals, but the court later upheld EPA's right to require states to develop plans. At this point, although the court has ruled that the states must complete the plans, it has not ruled on when the plans must be done. EPA is now seeking the court's permission to move forward with the deadlines that were in the initial rule. The court also ruled that EPA must revise the emission budgets for Georgia and Missouri and Wisconsin. Industry and opposing states are continuing to get decisions reversed, which is unlikely at this point. The map above illustrates the status of power plant cleanup in the Eastern U.S.

If the full emission reductions are not achieved from power plants, states may find it very difficult to meet the eight hour ozone standard. In addition, they will make it difficult for downwind states to comply with the federal ozone standard.

Cleaner diesel: Require clean engines and fuel

Diesel trucks and buses are a growing part of the pollution problem in the United States. Currently, diesel trucks and buses are responsible for 34% of the emissions from on-highway vehicles, although they make up only 2% of the registered vehicles on the road. Over the past 30 years, emissions from diesel trucks have increased 60%. In comparison, emissions from cars have decreased 42% over that same period.¹⁸ Cars are much cleaner today because lead was taken out of gasoline, allowing manufacturers to install catalytic converters and other emission control equipment over the years.

In 30 years little has been done to clean up diesel engines however. In fact, diesel fuel is so dirty that trucks are not able to use any catalytic converters to control NOx and other emissions at this time. In May 2000, EPA proposed to clean up diesel fuel and engines beginning in 2007. The Clean Air Network and other environmental and health organizations hailed this proposal as a good and long overdue act. Specifically, the proposal would:

- **reduce sulfur levels in diesel fuel by 97%.** Sulfur acts like lead to poison catalysts, making it impossible to use pollution control equipment. Also like lead, levels must be reduced to nearly zero in order to have an impact on emissions from trucks and buses. Because dirty fuel can destroy the catalyst, all fuel must be clean by mid-2006 so that model year 2007 trucks can use it without fear of damage to the engine.
- **reduce emissions from diesel engines by 95%.** With cleaner fuel, trucks can be considerably cleaner. EPA, by taking an integrated approach to the fuel and engine system, was able to propose cleaning up truck and bus emissions so that they will be more in line with the level of emission reductions that have already occurred for cars over the past 30 years.
- **provide incentives for manufacturers to go beyond the requirements of the proposal.** EPA is proposing to create a "Blue Skies" certification option for manufacturers that make engines cleaner than the proposed requirements. Similar to the Energy Star program for appliances and computers, this would allow consumers and manufacturers to choose to buy cleaner products that use advanced technology.

Setting the most stringent standards possible for diesel engines must be a national priority. First, diesel exhaust is a probable human carcinogen, and is responsible for more than 1/3 of the on-road vehicle emissions that cause smog. Second, the average diesel engine has a life of over 1,000,000 miles. EPA has put forth an aggressive proposal to clean up diesel engines and fuels. We must stress that cleaning up diesel fuel holds the key to cleaning up emissions. Diesel fuel refiners and retailers are pushing very hard to relax sulfur requirements, reducing sulfur levels but not to levels necessary to use catalytic converters. There is no room for compromise on sulfur levels if we are going to clean up engine emissions. Sulfur must be removed to near zero levels to make this proposal go forward. EPA plans to finalize the diesel rule by the end of 2000.

Conclusion

Ozone smog is a serious health and environmental threat. Over the past few years, it has become even more apparent that we face a national, not just an urban, problem. We need to move forward with strong national and regional programs to clean the air to levels that are safe for our children and environment.

This year offers a number of opportunities to address long-term and emerging smog problems with powerful solutions. Within the next year, EPA will determine the areas out of compliance with the ozone standard, based on data collected in 1997-99. There are 333 counties in 33 states that have monitored dirty air over the past three years and will be designated as being in nonattainment of the 8-hour ozone health standard. It is clear that this is not an isolated problem, but one that the nation as a whole needs to tackle.

In addition, EPA and states will make decisions this year that will set a course to reach clean air goals. If EPA adopts strong nationwide rules to clean up diesel trucks, buses and fuels, one of the largest sources of pollution will be much cleaner in the future. If eastern states commit to cleaning up power plants, the largest industrial polluter will emit less smog-forming pollution. But if we fall short, the task of making the air safe to breathe will be much harder and more costly for all of us. We owe it to the future to act now to clear the air.

Appendix A: Explanation of Data

This is the main data table from which other tables are derived. Data was obtained from the U.S. Environmental Protection Agency's Office of Air Quality Planning and Standards in May, 2000. This is the data set that EPA and states are using to determine if monitors are in nonattainment or attainment of the 8-hour ozone standard.

Explanation of the columns:

State - Name of state

County - Name of county

Area location or site address - Where monitor is located

Metropolitan Statistical Area or County if V - For all counties violating the ozone standard, the Network compared counties in violation of the ozone standard with counties in U.S. Census Bureau-defined Metropolitan Statistical Areas. If a county was not part of an MSA, it was listed as a county. In the case of nonattainment designations, if a monitor is in violation of the ozone standard, the entire county or MSA is the presumptive boundary for the nonattainment area unless the state can provide detailed justification for drawing a smaller or larger area.

The Clean Air Network used "Metropolitan Counties in Alphabetical Order, By State, with Metropolitan Title" table, by the U.S. Census Bureau, available at <http://www.census.gov/population/estimates/metro-city/a99mfips.txt> to create this field.

Design Value - This is the three year average of the fourth highest maximum ozone value. If design value is above 85 parts per billion, the monitor is in nonattainment of the ozone standard.

Note (*/)** - Indicates irregularities in 1997-99 data not complete, and how EPA is looking at this monitoring site. Monitors with * denote that because data was not complete in 1999, EPA will be using data from 1996-98 to determine nonattainment. Monitors with ** denote that three consecutive years of data are not available at this monitor, but the two-year average is at or above 85 ppb and is likely to be in nonattainment if trends continue. Nonattainment status is based on any three consecutive years of data as a rolling average.

Viol? (V) - All monitors with a design value at or above 85 ppb is considered to be in violation of the ozone standard.

4th Max 8-Hour Avg. - The National Ambient Air Quality Standard for ozone is based on the 4th highest daily value over the course of the year. This value is then averaged over a three-year average to determine the design value. Therefore, we have listed the values in 1997, 1998, and 1999 that are averaged to determine if the monitor is in nonattainment or attainment. Due to space limitations, we did not provide data from 1996 but is available upon request.

8-Hour Days > = 85ppb - This lists the total number of days each year that the ozone levels were above 85 ppb. If there is a dot in the column, it means there were no days when the ozone levels were above the standard. The final column, 97-99, adds the number of dirty air days over the three year period.

NOTES:

* Design value based on 1996-98 values since 1999 data is incomplete.

** 2 years of data with a potential to violate. 2-year design value listed in "Notes" column.

***To facilitate viewing, these design values and annual fourth maximum values are reported in parts per billion (ppb). However, the form of the 8-hour ozone National Ambient Air Quality Standard is parts per million (ppm) and the NAAQS requires reporting of air quality monitoring data in ppm. The correct form of the data would actually be presented in ppm based on the form of the 8-hour ozone standard that appears in 40 CFR 50.10. For consistency with the NAAQS, all manipulations of air quality data to derive design values and draw conclusions about the status of a location must be performed in ppm.

****For sites in which the design value is based on 1996-98 data, total exceedances are for 1996-98 also.

Days with maximum 8-hour average greater than or equal to 85 ppb are the total days in 1997-1999 where the maximum 8-hour values are greater than or equal to 85 ppb. County exceedances are based on the site wth the maximum number of exceedances for the county. The exceedances are based on information in AIRS in April and have not been checked.

If a site is violating with 3 years of data, it is given priority over a site potentially violating with 2 years of data.

V=violating (Design value is greater than 0.08 ppm.)

The Location is a general guide to where the county is located. For counties not located in a MSA, they may be adjacent or near to other MSAs besides those listed.

NOTES:

* Design value based on 1996-98 values since 1999 data is incomplete.

The Clean Air Network is an alliance of national, state and local environmental, public health and citizen organizations concerned about clean air. We empower and mobilize organizations by setting a national agenda and providing the resources, tools, and support necessary for action.

Initiated by The Pew Charitable Trusts through a grant to Pace University, CLEAR THE AIR is a joint project of three leading clean air groups, the Clean Air Task Force, National Environmental Trust and U.S. PIRG Education Fund.
